

CHEM 1300/1310

Formal Charges

- either positive or negative charge on a given atom in a compound
- must draw the charge on the atom (if a charge exists)

$$\text{Formal charge} = \# \text{ of valence } e^- - \# \text{ of } e^- \text{ atom actually has}$$

(group # on periodic table) or

$$\# \text{ of valence } e^- - \frac{1}{2} \# \text{ of shared } e^- - \# \text{ of unshared } e^-$$

EX:

Find the formal charge of the Oxygen atom

$$\text{FC} = 6 \text{ valence } e^- - 7 e^- \text{ it actually has} = -1$$

$$= 6 \text{ valence } e^- - \frac{1}{2}(2 \text{ shared } e^-) - 6 \text{ unshared } e^- = -1$$

Therefore, it would be drawn like this:

referring to the covalent bonds referring to the lone pairs

indicating its formal charge

When carbon has a formal charge:

a positive formal charge

-has one less electron, so only 3 e⁻

can only form 3 bonds

vs a negative formal charge

-has one more electron, so 5 e⁻

can only form 3 bonds b/c

*carbon can NEVER have 5 bonds

so the 2 remaining electrons form a lone pair (nonbonding electrons)

Keeping these rules in mind, it

is possible to determine how many H atoms are on the carbon.

No H atoms

1 H atom

2 H atoms

No H atoms
